abortion, the relative risk of breast cancer was 1.03 (95% CI 0.89-1.18), compared with women who had never had an induced abortion. The corresponding relative risk for spontaneous abortion was 0.98 (95% CI 0.92-1.04).

In contrast to the findings of many retrospective studies, the prospective studies suggest that induced or spontaneous abortions do not increase a woman’s risk of breast cancer.

Effects of conjugated equine estrogen in postmenopausal women with hysterectomy. The Women’s Health Initiative Randomized Controlled Trial. JAMA 2004; 291: 1701–1712

This study was one of two parallel, randomised, double-blind, placebo-controlled trials designed to test the effects of this type of hormone replacement therapy (HRT) on chronic disease. The National Heart, Lung and Blood Institute in the USA set the study up 13 years ago. The oestrogen plus progestogen arm of the trial was halted in July 2002 due to increased risk of coronary heart disease, thromboembolic disease and breast cancer. This arm of the trial compared use of oestrogen only HRT (conjugated equine oestrogen) with placebo in nearly 11 000 women aged 50–79 years. The study was stopped a year before its scheduled conclusion, even though no predefined boundaries had been crossed. There was also a high degree of non-compliance: 50% by the seventh year. The study provided us with some important information. The treatment group had a 39% increased risk of stroke compared to the non-treatment group (44 vs 32 per 10 000 person-years). Contributing factors may have been the small but persistent increase in blood pressure and the known effect of oestrogen on increasing the risk of thrombosis. There was a reduction in low-density lipoproteins (LDLs) and an increase in high-density lipoproteins (HDLs) but no impact on coronary heart disease incidence. Oestrogen reduced the risk of fractures by 30% to 39% (11 vs 17 per 10 000 person-years) in the treatment group. They reported a lower rate of breast cancer in the treatment group compared to placebo. This particular result is contrary to the oestrogen plus progestogen arm of the Women’s Health Initiative (WHI) trial and clearly needs further investigation. The small numbers may have confounded the results. Two components of the WHI on the effects of a low-fat eating pattern, and the effects of calcium and vitamin D supplements are still awaiting publication. For the present time, this study contributes further weight to the advice that HRT should be used for short-term relief of vasomotor symptoms only.

This is a community intervention study designed to determine whether offering advanced supplies of emergency contraception (EC) to large numbers of women influenced the abortion rates. In one area of Scotland women between 16 and 29 years were targeted through health services to be allowed to take home five courses of EC to keep when needed. There were 85 000 women in the target age group of whom 17 800 took a supply of EC home. Some 45% of this group took at least one course of the EC provided. The authors state that they have low abortion numbers in the intervention area (<2000 per year of the target group) and also reported that they had a high uptake of contraception in the area but numbers are not given. The results of the intervention did not reduce the abortion rate when compared with other areas of Scotland without any intervention.

In their discussion the authors did not emphasise that the EC used was Schering PC4 which is now not available. Levonelle® is now prescribed as it has been shown to be more effective but by how much is debatable. If the area targeted had a high uptake of contraception use then women probably were not aware of their pregnancy risks when using other methods so did not use EC when necessary. This study shows that no matter what we do as clinicians, we cannot predict what contraceptive users will do and how competently they can recognise when they are at risk of pregnancy.

The study raises concerns that sexually active young people are given messages that EC is available if they have a pregnancy risk but this study may indicate that by making EC readily available this still will not impact on the abortion figures. Abortion figures will only reduce when the sexually active population are motivated to use more effective long-term methods of contraception where EC is rarely needed.

BOOK REVIEWS

The X in Sex: How the X Chromosome postmenopausal women with hysterectomy.

The author’s engaging style makes it clear that women’s sex determination in a fascinating wider context. Who would have thought that many doctors might also find it helpful. The home page gives some news items, together with a search box and some drop-down menus. The menus are headed Tests, Conditions and Diseases and Screening, so that information about individual tests or conditions can be located. On the right-hand side is more general information such as how to interpret the terms used in tests (like reference ranges) and tours of what happens to samples when they reach the laboratory. There is also a feedback page and the site is peer-reviewed, we have over-interpreted when presented to the public. There is no suggestion that this too needs addressing.

The book is divided into two halves. The first deals with the effects of drugs on the causation of sexual problems and the second addresses drug treatment for sexual problems. The introduction to the treatment of premature ejaculation says: ‘None of the mentioned agents has been approved by the FDA for the treatment of PE’ It seems unusual to devote a whole chapter on treatment to unlicensed drugs.

Having felt cause to argue in particular with the way things are said in this book, I do think it has some use in presenting pharmaceutical information about sexual function. Perhaps that is after all what it intended to do.
